

Acid Rain Program Emissions Scorecard 1997

*SO₂, NO_x, Heat Input, and CO₂ Emission Trends
in the Electric Utility Industry*

Background

Acid Rain Program Overview

Established under Title IV of the Clean Air Act Amendments of 1990, the Acid Rain Program requires the electric utility industry to reduce emissions of sulfur dioxide (SO₂) and nitrogen oxides (NO_x), the pollutants that cause acid rain. To ensure that the desired emission reductions are achieved, the program implements an innovative market-based regulatory approach with utilities having flexible compliance options. The program, administered by the U.S. Environmental Protection Agency (EPA) was designed to be implemented in two phases: Phase I (1995 through 1999) and Phase II (2000 and beyond). Phase I requires emissions reductions from the highest-emitting units at 110 large power plants, while Phase II includes utility units and combustion turbines at more than 700 additional plants.

After each calendar year, EPA determines the compliance of each facility relating to its SO₂ and NO_x emissions requirements and publishes a report documenting the results. The compliance results for calendar year 1997 for Phase I affected plants are presented in the Acid Rain Program 1997 Compliance Report (EPA-430-R-97-031), published in August 1998. The Compliance Report further describes the Acid Rain Program's market-based regulatory approach and compliance options. EPA also prepares this annual "Scorecard" report which contains comprehensive summary data and trends information from all Title IV affected facilities.

To ensure that nationally mandated reductions in SO₂ and NO_x emissions are achieved and documented, the Acid Rain Program regulations require most affected facilities to install Continuous Emissions Monitoring (CEM) systems at their plants to measure and record data for SO₂, NO_x, carbon dioxide (CO₂) emissions, and volumetric flow data, along with other relevant information. The Acid Rain Program regulations also require facilities to conduct a series of initial and ongoing quality assurance tests on each of their CEM systems to ensure the accuracy of the measured emissions. After each calendar quarter, affected facilities must assemble the recorded data into a comprehensive emissions report and submit the report to EPA.

The Scorecard: Emissions Data Collection and Evaluation

Much of the data contained in the Acid Rain Program's Scorecard are derived from the Emissions Tracking System (ETS). EPA developed ETS to collect, analyze, and archive the quarterly emissions reports and associated data submitted by the affected facilities. ETS now contains a substantial emissions database since Phase I affected facilities began reporting data in January, 1994, and Phase II facilities began reporting data in May, 1995.

The primary function of ETS is the routine processing of the emissions reports received by EPA after the end of each calendar quarter. ETS analyzes each emissions report and generates results that are forwarded to the facility. These results indicate any potential problems detected in the hourly, quarterly, and year-to-date emissions and heat input data values. Other data contained in the report, including quality assurance test data and monitoring plan information, are also analyzed. In some cases, facilities may need to correct problems and resubmit quarterly reports to EPA.

After the end of a calendar year, EPA uses the year-to-date values contained in ETS for all Title IV affected units as the starting point for creating the Scorecard. Numerous quality checks are performed on the reported data, such as verifying data consistency and comparing current values to historical values. After the data are evaluated and quality assured by EPA, facilities have an opportunity to review and comment on EPA's understanding of their data. Once the data are finalized, EPA prepares annual statistics and develops trends data for the Scorecard.

Trends in SO₂ Emissions and Heat Input, 1980 to 1997

The long term trend in SO₂ mass emissions for all units affected under Title IV is shown in Figure 1 (the data are displayed at five-year intervals from 1980 to 1995, followed by 1996 and 1997). Emissions declined gradually by 9.1% or about 1.6 million tons between 1980 and 1990, followed by a sharp drop of about 24.7% or 3.9 million tons from 1990 to 1995, which was the first year Phase I units were required to comply with the Acid Rain Program. This emissions drop was then followed by increases of approximately 5.7% or 670,000 tons in 1996 and of 3.8% or 470,000 tons in 1997. This increase in emissions is attributable primarily to increased utilization.

**Figure 1**

National SO₂ Emissions Trend for all Title IV Affected Units

Figure 2
Phase I, Table 1 Unit SO₂ Emissions Trend

Figure 2 shows the SO₂ emissions trend for the 263 units required to participate in Phase I of the program ("Table 1" units) over the same time period (including data from 1994). The emissions trend exhibited by the Table 1 units is similar to the national emissions trend shown in Figure 1, as the steep decline in SO₂ emissions in 1995 is due primarily to emission reductions at the Phase I units. A significant portion of the increase in national emissions from 1996 to 1997 was due to increased emissions from the additional Phase I units (compensating, substitution, and opt-in) and the Phase II units. This is in contrast to the change between 1995 and 1996, where increased emissions nationwide were due to increased emissions from Table 1 units.

For 1995 through 1997, SO₂ emissions for Table 1 units fell below their allowable level for each year. In 1995, the Table 1 units emitted 2.9 million tons less than the allowable level for 1995 (7.4 million tons). In 1996, the Table 1 units emitted 2.3 million tons less than the 1996 allowable level of 7.1 million tons. The 1997 emissions for Table 1 units were 1.2 million tons below the allowable level of 6.0 million tons.

There are several reasons for the continued rise in emissions in 1997. One reason is that the increase in emissions was consistent with a general increase in coal-fired electricity generation and a decline in generation by nuclear power and natural gas from 1995-1997. In 1996 and 1997, emissions from utility coal-fired units represented 97% and 96% of the total emissions. Data presented in the 1997 Volume 1 *Electric Power Monthly*, by the Energy Information Administration (EIA), indicated that electric utility coal-fired generation increased 5.11% in 1996 and 2.95% in 1997, almost precisely the same as the increases in SO₂ emissions reported to EPA. Using coal instead of non-coal fuels (gas, oil, wood, etc.) for electricity generation causes higher amounts of SO₂ emissions. In 1997 for Table 1 units (97% coal fired), the average SO₂ emissions were 18,137 tons per unit compared to an average of 4,745 tons per unit for the additional Phase I units (compensating, substitution, and opt-in) and the Phase II units.

Figure 3
National Heat Input Trend for all Title IV Affected Units

Another likely reason that emissions rose was due to increased demand for (and generation of) electricity. Figure 3 shows the trend in heat input (a measure of fuel burned to produce electricity) for all Title IV affected units.

Based on the heat input trend illustrated in Figure 3, it appears that electricity production for all Title IV affected units increased by an average of 1.9% per year since 1980. From 1996 to 1997 the increase in heat input for electrical

production averaged 4.0%, accompanied by a comparable 3.8% increase in national SO₂ emissions.

The final reason for the increase in SO₂ emissions in 1997 is the significant over compliance in 1995, the first compliance year for the Acid Rain Program. In 1995, all Phase I units emitted 3,440,000 tons less than the total number of 1995 allowances available, enabling units to save, or “bank,” these unused allowances for future use. In 1996, SO₂ emissions increased so that only 2,860,000 allowances were banked. In 1997, the emissions for all Phase I units increased resulting in 1,680,000 allowances being banked. Apparently some facilities found it more economical to use more allowances for compliance in 1996 and 1997 (perhaps because allowance prices were lower than predicted) instead of controlling their SO₂ emissions to the same degree as in 1995.

Trends in NO_x Emissions, 1995-1997

1996 was the first year Phase I units were required to limit their NO_x emission rates under the Acid Rain Program. National NO_x mass emissions declined by 570,000 tons from 1990 to 1995 and by an additional 180,000 tons from 1995 to 1996, despite the increase in heat input shown in Figure 3. In 1997, national NO_x mass emissions increased about 130,000 tons from 1996 due to increased utilization. Figure 4 shows the estimated NO_x mass emissions for all Title IV affected units for 1990, 1995, 1996 and 1997.

Figure 4

National NO_x Emissions from 1990, 1995 through 1997 for all Title IV Affected Units

NOTE: In 1995 certain non-coal-fired Title IV affected units were exempted from reporting NO_x data for a portion of the year; their annual NO_x emissions were estimated from the partial-year data. For 1995 and 1996, the NO_x mass emissions were calculated by multiplying the unit's average annual NO_x emission rate (lb/mmBtu) by its total annual heat input (mmBtu), and dividing by 2000 to convert to tons. In 1997, the NO_x mass emissions were calculated by multiplying the unit's average hourly NO_x emission rate (lb/mmBtu) by the hourly heat input (mmBtu/hr) and unit operating time (hr), and dividing by 2000 to convert to tons. All of these values are reported to EPA by facilities in their quarterly submittals.

Under the Acid Rain Program, the NO_x emissions limit applicable to a particular coal-fired unit is determined by the boiler firing type. Starting in 1996, Phase I tangentially fired coal units were required to limit their NO_x emissions rate to 0.45 pounds per million British thermal units (lb/mmBtu), and dry bottom wall-fired coal units were required to limit their NO_x emission rates to 0.50 lb/mmBtu. These emission rates do not have to be achieved by each unit individually; facilities have the flexibility to enter into emissions averaging

Figure 5

Average NO_x Emission Rate (lb/mmBtu) for 1990, 1996 and 1997 by Boiler Type for all Tangentially Fired and Wall-Fired Title IV Affected Units

Figure 6

National CO₂ Emissions Trend for all Title IV Affected Units

Table 1

National Totals of SO₂, NO_x, CO₂, and Heat Input for Coal Fired and Non-Coal Fired Title IV Affected Units for 1996 and 1997

Pollutant/Heat Input	Year	Coal	Non-Coal	Total
SO ₂ (Tons)	1996	12,105,081	408,782	12,513,863
	1997	12,511,081	467,046	12,978,127
NO _x (Tons)	1996	5,541,584	386,768	5,908,352
	1997	5,616,471	426,189	6,042,660
CO ₂ (Tons)	1996	2,010,972,798	220,460,260	2,231,533,058
	1997	2,064,871,688	238,520,194	2,303,391,882
Heat Input (mmBtu)	1996	19,510,824,887	3,315,745,968	22,826,570,855
	1997	20,092,477,956	3,647,002,918	23,739,480,874

plans in which the average NO_x emission rate of participating units must be below the applicable emission limit. More information on the NO_x program is available at the Acid Rain Program web site (www.epa.gov/acidrain).

Figure 5 shows the 1990, 1996 and 1997 heat input-weighted average NO_x emission rates for all units reporting to the Acid Rain Program, by boiler type. The 1997 average NO_x emission rates have remained almost the same as the 1996 average NO_x emission rate for both tangentially-fired (0.36 lb/mmBtu) and wall-fired units (0.43 lb/mmBtu). These emission rates are below the required limits set for Phase I NO_x affected units of 0.45 and 0.50 lb/mmBtu.

Trends in CO₂ Emissions, 1995-1997

Title IV does not require control of CO₂ emissions; it only requires that they be measured and reported. As indicated in Figure 6, emissions of CO₂ from all Title IV affected units increased by 2.8% from 1995 to 1996 and by an additional 3.1% from 1996 to 1997.

Emissions Data Summary for 1997, by Fuel Type and Phase

Table 1 presents the 1996 and 1997 national total emissions and heat input data for all Title IV affected units, apportioned by two broad primary fuel type categories (coal or non-coal). The data reflect the predominance of coal use by U.S. facilities. Of the national totals in 1997, coal units account for 85% of the heat input, 96% of SO₂ emissions, 93% of NO_x emissions, and 90% of CO₂ emissions. Non-coal units affected by the Acid Rain Program include those that burn liquid or gaseous fossil fuel (oil, diesel, natural gas, etc.) or other solid fuel (one unit combusts wood) as their primary fuel.

Table 2 shows SO₂ emissions by three categories of units: 1) those 263 units required to participate beginning in 1995 (Phase I, table 1 units); 2) those units that were not affected by the program, but chose to participate (opt-in) or are Phase II units that chose to fall under the Phase I requirements (Phase I, voluntary participants: compensating or substitution units); and 3) those units not required to comply until 2000 (Phase II units). Phase I, Table 1 units had no change in emissions between 1996 and 1997. The voluntary participants in Phase I units and the Phase II units had increased emissions of 5.97% and 6.08%, respectively, between the same two years, resulting in total SO₂ emissions increasing by 3.71% or 464,264 tons.

	1996 SO ₂		1997 SO ₂	
	Number of Units	Emissions (millions tons)	Number of Units	Emissions (millions tons)
Phase I, Table 1	263	4.77	263	4.77
Voluntary Phase I, Substitution, Compensating and Opt-In Units	168	0.67	160	0.71
Phase 2	1,473	7.07	1,485	7.50
Totals	1,904 *	12.51	1,908 *	12.98

* Total number of units with emissions

Table 2

SO₂ Emissions Breakdown by Program Participation of Units for 1996 and 1997

Data Quality Assurance

A major component of the success of the Acid Rain Program is the high degree of confidence in the allowance market. The Acid Rain Program supports this confidence by requiring affected facilities to perform and report quality assurance tests for each of their monitoring systems. These quality assurance tests ensure accurate and continuous emissions monitoring and reporting.

There are two basic types of monitors used in the Acid Rain Program: pollutant monitors and flow monitors. Quality assurance tests must be performed for both of these monitor types. Pollutant monitors measure the concentration of a pollutant present in the stack gas emitted from a unit, while flow monitors measure the volume of the emitted stack gas or volume of fuel used. The pollutant concentration data and flow data are then used to calculate emissions values. Table 3 summarizes the results for key emissions measurement quality assurance measures for 1995, 1996 and 1997.

Table 3*Emissions Measurement Quality Assurance Measures*

Quality Assurance Measure	1995	1996	1997
Percentage of RATA test results indicating < 7.5% relative accuracy for pollutant monitors	94.5%	94.5%	96.0%
Median Relative Accuracy for pollutant monitors	3.22%	3.06%	3.27%
Percentage of RATA test results indicating < 10% relative accuracy for flow monitors	95.0%	95.8%	95.8%
Median Relative Accuracy for flow monitors	3.85%	3.54%	3.47%
Mean Annual Percent Monitor Availability	95.5%	96.7%	97.7%
Median Annual Percent Monitor Availability	98.4%	99.0%	99.2%
Number of Actual CEMS Used (except CO ₂)	4,364	4,149	4,185

Note: The RATA test results data were omitted where reporting errors occurred

The first key quality assurance measure is the accuracy of emissions monitors. Every six months facilities are required to perform relative accuracy test audits (RATAs) on all monitors used in the Acid Rain Program, and then calculate and report the relative accuracy (%). The relative accuracy indicates how much the monitored values differ from values calculated using a standard reference method during the test. If a monitor is found to systematically under-report pollutant or flow data, the facility must correct this "bias" by applying an adjustment factor to the data reported from the monitor. This "bias adjustment factor" ensures that emissions data are not under-reported.

Pollutant monitors must demonstrate a relative accuracy of less than 10% (the lower the relative accuracy, the more accurate the monitor). As an incentive to improve and maintain their monitor relative accuracy, a facility is allowed to test a pollutant monitor only once every 12 months (instead of every six months) if its relative accuracy is below 7.5%. As Table 3 indicates, 96% of pollutant monitors qualified for the annual testing in 1997, an increase of 1.6% from both 1995 and 1996. The median relative accuracy (which EPA believes to be a better measure of central tendency than the mean for this data) for these monitors dropped to 3.27% in 1997 from 3.06% in 1996.

Flow monitors must demonstrate, during Phase I, a relative accuracy of 15% and can qualify for annual testing if their relative accuracy is below 10%. As Table 3 indicates, over 95% of flow monitors qualified for the annual testing from 1995 through 1997, and the median relative accuracy for flow monitors improved to just below 3.5% in 1997. Overall, the median relative accuracy of less than 3.5% for all monitors used in the Acid Rain Program strongly indicates the emissions data presented here are the most accurate of their kind.

A second key quality assurance measure is the "percent monitor availability" (PMA) data shown in Table 3. PMA indicates the percentage of unit operating hours for which measured, quality-assured data were collected by the facilities. If the data cannot be reported by a quality-assured monitor, the facilities must use EPA-developed algorithms to calculate and report substitute data values until quality-assured data are available. The calculated median PMA improved from 98.4% in 1995 to 99% in 1996 then to 99.2% in 1997. This high availability level emphasizes that CEMS are a mature and reliable technology for the measurement of atmospheric emissions. Finally, Table 3 shows the number of CEMS actually used (not just installed) to report data during 1995, 1996 and 1997.

Detailed Emissions Results for Acid Rain Program Affected Units

Detailed tabular results for the Acid Rain Program are presented in Appendices A and B. The following is a description of the contents of the Appendices.

Appendix A

.....
Consists of two data tables: Table A1 and Table A2.

Table A1 presents the annual SO₂ emissions and heat input data for all Title IV affected units for the following years: 1980, 1985, 1990, 1996 and 1997. The data are ordered alphabetically, first by State name and then by plant name within each State. A unique numeric code used to identify each plant, known as the "ORISPL" code, is included in a column adjacent to the plant name. The column labeled "Unit ID" identifies the unit within the plant for which data are reported. The "Parent" column identifies any stack or pipe associated with this unit.

The SO₂ and heat input data for each plant listed in Table A1 are displayed at the unit level, or "Unit ID", within the plant. In cases where different types of monitors are located at different sites within a plant or the connections between units and stacks are complicated, the data have been assimilated to the basic (unit) level for ease of presentation and comparison. In the case where a stack is fed by more than one unit, the stack is referred to as a "common stack" and is prefixed by "CS" in the "Parent" column (the constituent units are listed in parentheses). A stack/unit arrangement where a stack is fed by more than one unit, any of which feeds another stack is called a "complex stack" and is prefixed by "XS" in the "Parent" column

(again, the constituent units are listed in parentheses). Analogous definitions apply to common fuel pipes ("CP" prefix) and complex fuel pipes ("XP" prefix). If a single unit feeds multiple stacks, the stack values are combined and listed at the unit level. Any ID listed in the "Parent" column that does not contain any of the aforementioned prefixes refers to an individual unit.

Table A2 provides State-level summaries of the annual SO₂ and heat input data, for 1980, 1985, 1990, 1996, and 1997. The resulting national totals for those years are also presented at the end of the table.

Appendix B

.....
Consists of four data tables: B1, B2, B3, and B4.

Table B1 presents the total annual 1997 SO₂, NO_x, CO₂, and heat input data for all Title IV affected units, along with additional descriptive information. The data are ordered alphabetically, first by state name and then by plant name within each state. A unique numeric code used to identify each plant, known as the "ORISPL" code, is included in a column adjacent to the plant name. The column labeled "Unit ID" identifies the unit within the plant for which data are reported. The various "Unit ID" definitions used in Table B1 are discussed below. The "Parent" column identifies any stack or pipe associated with the unit.

The SO₂, NO_x, CO₂, and heat input data for each plant listed in Table B1 are displayed for the unit locations, or "Unit ID", within the plant. In cases where different types of monitors are located at different sites within a plant or the connections between units and stacks are complicated, the data have been assimilated to the basic (unit) level for ease of presentation and comparison. In the case where a stack is fed by more than one unit, the stack is referred to as a "common stack" and is prefixed by "CS" in the "Parent" column (the constituent units are listed in parentheses). A stack/unit arrangement where a stack is fed by more than one unit, any of which feeds another stack is called a "complex stack" and is prefixed by "XS" in the "Parent" column (again, the constituent units are listed in parentheses). Analogous definitions apply to common fuel pipes ("CP" prefix) and complex fuel pipes ("XP" prefix). If a single unit feeds multiple stacks, the stack values are combined and listed at the unit level. Any ID listed in the "Parent" column that does not contain any of the aforementioned prefixes refers to an individual unit.

NOTE: Table B1 displays both the average NO_x emission rate (lb/mmBtu) and the NO_x mass emissions (tons). Under the Acid Rain Program facilities are only required to report the average NO_x emission rate. As a result, the NO_x mass emissions values contained in the table were calculated by weighting the hourly average NO_x emission rate (lb/mmBtu) by hourly heat input (mmBtu/hr) and the operating time, and then dividing by 2000 to convert the resulting value to tons.

Table B1 also contains five columns that provide descriptive information (in a coded format) about each Unit ID listed. These columns are labeled "Phase," "Status," "Primary Fuel," "SO₂ Controls" and "NO_x Controls," and their associated codes are described below:

Phase describes the Acid Rain Program "phase" classification for each stack or unit. The phase codes are defined as follows:

- P1** Phase I, Table 1 unit (263 units)
- P1.5** Phase I, Non-Table 1 unit (e.g., a Phase II unit that elected to become a Phase I substitution unit or compensating unit for a Table 1 unit as a compliance option in 1997, or a unit that opted-in to the program for 1997)
- P2** Phase II unit

Status describes the operating status of each stack or unit. The status codes are defined as follows:

- DF** Deferred unit, did not operate in 1997 (typically has been in long-term shutdown since before 1995), but is affected under Title IV
- RE** Retired unit
- FU** Future unit (planned or under construction), will be affected under Title IV when operational
- NO** Non-Operating unit, plant did not operate during 1997
- N** New Non-exempt (new to the program and may not be operational-next stage beyond FU (future)
- Blank** Operational (no permit exemptions), affected under Title IV

Fuel describes the primary fuel used by each unit. The fuel types are:

- C** Coal
- O** Oil
- G** Gas
- D** Diesel
- W** Wood
- NR** Primary fuel type was not reported for the Unit ID

SO₂ Controls describes the type of SO₂ control technology (scrubber), if any, reported as installed as of the end of 1997 for the Unit ID. Facilities employ these controls in order to assist or assure compliance with SO₂ emission requirements under the Acid Rain Program or other regulatory programs. The control codes are defined as follows:

DA	Dual alkali
DL	Dry lime FGD (flue gas desulfurization)
MO	Magnesium Oxide
O	Other
SB	Sodium based
U	Uncontrolled
WL	Wet lime FGD
WLS	Wet limestone
Blank	No information reported for the Unit ID

NO_x Controls describes the type of NO_x control technology, if any, reported as installed as of the end of 1997 for the Unit ID. Facilities employ these controls in order to assist or assure compliance with NO_x emission requirements under the Acid Rain Program or other regulatory programs. The control codes are defined as follows:

LNB	Low NO _x burners without overfire air
LNBO	Low NO _x burners with overfire air
LNCB	Low NO _x burner technology for cell burners
LNC1	Low NO _x coal and overfire air option 1
LNC2	Low NO _x coal and overfire air option 2
LNC3	Low NO _x coal and overfire air option 3
CM	Combustion modification with fuel reburn
SNC	Selective non-catalytic
SNCR	Selective non-catalytic reduction
SCR	Selective catalytic reduction
O	Other
U	Uncontrolled
OFA	Overfire air
Blank	No information reported for the Unit ID

Table B2 provides Plant-Level summaries of the 1997 SO₂, NO_x, CO₂, and heat input data by state. The resulting totals for each plant are represented and state totals are represented after each state listing.

Table B3 provides State-level summaries of the 1997 SO₂, NO_x, CO₂, and heat input data for *coal-fired units*. The resulting national totals for coal-fired units is presented at the end of the table.

Table B4 provides State-level summaries of the 1997 SO₂, NO_x, CO₂, and heat input data for *non-coal-fired units*. The resulting national totals for non-coal-fired units is presented at the end of the table.
